Preface

Advances in technology are making it imperative to collect and diagnose detailed structural IC fail data during manufacturing test to improve yield. However, current datalog formats (STIL and STDF V4) do not have efficient support for storing structural fail information. In particular STDF V4 which is widely used for functional and parametric datalogging does not have any intrinsic support for storing scan and memory fail requirements. Lack of any standard format to store these fails leads to many custom formats and corresponding translators which results in un-necessary investments in development and maintenance as well as inefficiencies in the diagnosis process for yield learning.

In order to address the above mentioned problems, an extension of STDF V4 called STDF-V4 2007 has been defined to provide formats for storing scan and memory fails as well as for supporting the volume diagnosis flows. This document contains the specifications of this standard.

It is our hope that this standard will be useful to all the companies involved in diagnosing the structural fail information for yield learning and would adopt this into their tools and environments.

Glossary of Terms

ATPG	<u>A</u> utomatic <u>T</u> est <u>P</u> attern <u>G</u> enerator: A SW tool normally provided by EDA companies that is used to create the scan based test patterns eventually translated by and used on the ATE. Generally the ATPG tool will output this information as either a WGL, STIL file, or other proprietary language file.
STIL file	<u>S</u> tandard <u>T</u> est <u>I</u> nterface <u>L</u> anguage (IEEE1450): A file employing a standardized format for conveying test pattern, timing, and signal information (functional and/or structural)
WGL file	<u>W</u> aveform <u>G</u> eneration <u>L</u> anguage: A file employing a regular format for conveying test pattern, timing, and signal information (functional and/or structural)
Chain	ScanChain: A sequence of linked internal scan cells that in the context of test patterns have a discrete scan input and a discrete scan output with some number of scancells between the two.
Pattern	Sometimes confusing term because it is sometimes used in multiple contexts. In the structural test context, a pattern is the scanning in of a data sequence on the scan-in pins that sets all of the scan cells within the IC with a set of stimulus data, the execution of a “capture” cycle which transfer the results of the scan pattern test into the scancells, then shifting out and testing the test results on the scan-out pin. Typically the stimulus data for the next scan pattern is shifted on the same cycles that the data from the present pattern is being shifted out. A Pattern Block will contain several hundreds or thousands scan patterns. While a single STIL / WGL file can support multiple pattern block definitions, generally ATPG tools only include a single pattern block in each file. And in turn, a single test on the ATE may apply several pattern blocks, built from multiple ATPG files.
Pattern/Chain/Bit	Term that specifies that the scan failure data is being logged in context of the failing scan pattern #, chain # (via PMR index), and scancell position within the scan chain. This format is an alternative to logging the cycle # and PMR index which leaves it to the downstream diagnostic tool to convert this to the corresponding pattern/chain/bit information.
PMR Index	An arbitrarily numeric index that is assigned to each pin/signal used by the ATE to provide/monitor test data. PMR indexes must be > 0. STDF file records failures based on their PMR index. The

STDF **PMR** (**P**in **M**ap **R**ecord) record is used to provide textual information about a unique pin (one record per pin).

Signal	Synonymous with <i>Pin</i> . IC input/output pin name.
Scan Cell	Refers to the flipflop/latch that is used as the stimulus/observation node of a scan pattern.
Scan-In	The name of the signal(pin) on which scan data is applied to by the ATE
Scan-Out	The name of the signal(pin) on which scan data output is tested by the ATE
ScanStructure	A block of information that defines the structure of scan chains within the logic of an IC. This information will contain the list and attributes of each scan chain within the IC. Chain attributes generally include the ATPG signal names used for the Scan-In and Scan-Out functions, the # of scan cells within the chain, the clock(s) used to shift the data through the scan chain, and optionally the design instantiation name of each scan cell within the chain. When the latter is included, the size of a ScanStructure block can be significantly large.
Structural Test	A general term used for use of specialized on-chip test circuitry for testing the functionality of individual blocks of sub-circuits within an IC. Variations of structural test include Scan, Compressed Scan, BIST (logic Built-In-Test), MBIST (Memory Built-In-Test), and Boundary Scan.

Purpose

The purpose of this standard is to provide a common format for scan fail datalog specification along with necessary synchronization information enabling an efficient dataflow for volume diagnostics applications.

Background

Manufacturing yield is a very important factor in the production of a semiconductor product. It is important in all phases of the production: first silicon, volume ramp and normal production. Historically the yield fallout was mainly caused by random defects and process problems, so traditional yield improvement strategies included clean room improvements and process improvements. Correspondingly the data collection from ATE for yield monitoring was focused on parametric and gross pass/fail information collection. However, advances in technology have created a situation where yield loss is now dominated by the systematic design and process interactions, which are hard to understand before the silicon implementation. To understand these interactions requires fail data collection in volume manufacturing. Moreover, the design and pattern dependent nature of these issues requires fail data to be collected on the internal nodes using structural test techniques. Therefore the industry is moving toward Volume Diagnostics flow, where fail data on internal nodes is collected during volume manufacturing and processed by the diagnostic tools from the EDA vendors to identify the failing structures. The information on the failing structures is statistically analyzed to identify the yield improvement opportunities.

Figure 1 shows a flow for volume diagnostic mentioned above. In this flow the test patterns generated by ATPG tools from EDA vendors are applied to the production device by the ATE of choice. The ATE then collects the fail information in failure files.

Figure 1: Volume Diagnostics Flow

The failure information in these failure files is then used by the diagnosis tools to identify the failing structure, e.g., failing gate, failing via, failing net, etc. Currently the format in which these failure files are written depends on the ATE at hand. Each ATE vendor writes this information in a custom format.

Figure 2: Diagnosis in Multi-Vendor Multi-Tool Environment

To complicate the matters further, each diagnosis tool also has its custom input format. A multi-ATE and multi-diagnosis tools environment for a customer looks like the one shown in Figure 2. A customer in this situation has to create an IT infrastructure to store information in multiple formats-- one for each ATE and then translate this information into the input format of the corresponding diagnosis tool. The responsibility for developing and supporting the translation tools can be with the EDA vendors, ATE vendors, or the end users. The situation in the EDA and the ATE cases for a multi-tool, multi-vendor environment is shown in Figure 3 and Figure 4 respectively. In either case it is an extra

Figure 3: Format Mess, with ATE Custom Formats

Figure 4: Format Mess with EDA Custom Formats

overhead for the party responsible for developing and maintaining the conversion tools as well for the end user who has to deal with the conversion tools mesh/mess.

Desired Solution

The overhead associated with development and support of the conversion tools as well as with IT infrastructures can be eliminated if all the ATE could create failure files in a standard format and all the diagnosis tools can read the same standard format. This document describes the extension of STDF V4 that has been developed to serve this need as shown in Figure 5.

Figure 5: Standard Format Based Flow

Scope

- Scan fail datalog for volume diagnosis
- Fail logging at wafer as well as package test
- Format should allow capture of millions of failures (what one would expect in 2010)
- Format should support the design-test-design flow

Data Model for Scan Fail Datalog

Figure 6 shows a conceptual dataflow diagram for volume diagnostic applications as a base line for this standard. It shows how the test data flows through the design-to-test-to-design as well as transformations that the test data may undergo. As the data flows through the loop, the standard provides mechanisms to keep track of the changes to the extent that the design/diagnosis tools can correctly relate the fail datalog to the original files from which the test patterns were generated to perform correct diagnosis. Any changes to the test data in this loop can be communicated to the analysis tools using this standard. In addition the standard also supports representation of the information on the

conditions and equipment used to perform the test when the fail data was collected, to enable volume fail analysis over wafers/lots.

In particular, the standard allows following classes of information must be collected and supported by the format:

- Design Information
- Device Identification
- Test Identification (Test Flow, Test Suite, patterns)
- Test Environment (Temp, freq, volt, etc.)
- Transformation information for synchronization
 - Assignment of patterns to test suites
 - Addition/deletion/truncation of patterns on tester
 - Any Name mappings
 - Buffer full/ datalog truncation
- Format Specification for Fail data
- Fail and expect data and how the data is handled on ATE (For example how Z state is handled)

Figure 6: Conceptual Data Flow

Figure 7 shows an overview of the data model, containing data objects. Each of these objects will be described in the remaining part of this section with their intent and contents.

Figure 7: Data Model for Scan Fail Datalog

Design Information

The Design Information object allows the information related to design and DFT to be stored in the datalog. The design/DFT information that is relevant for volume diagnosis consists of:

- Design netlist identification
- Scan structure information.

Device Identification

The Device Identification Object information allows unique identification of the device for which the fail data is collected. Both wafer die and packaged part identification are supported. Device identification is required for statistical analysis of the diagnosis result for identifying any trends or correlation with other measurements. Wafer die identification data consists of:

- Wafer ID
- Lot ID
- XCoord, YCoord
- PartNumber
- Electronic ID

Package Identification data consists of:

- Serial Number
- Lot ID
- Die ID
- Electronic ID

FEH Identification

This class of data provides the unique identification of Front-End-Hardware (e.g., DUT boards, probes, etc.) that have been used to connect the product to the tester:

- Site ID: Which site the data was collected, e.g., Singapore, test facility
- Cell ID: The Test Cell where the testing was performed
- Prober/Handler ID: Identification of the prober/handler being used during the test
- LoadBoard ID: Identification of the loadboard being used during the test
- Optional field: Other environment-specific information can be added in the optional section.

Test Identification

Test Identification data allows unique identification of the test under which the fail datalog was collected. It contains the following information:

- Test Program Identification
- Test Stage Identification – e.g., Wafer Sort1, Wafer Sort2, Package, test number, etc.
- Test Suite Identification: This field identifies the test suite within a test flow as shown in Figure 8.
- Test Pattern Map : This data provides the information on how the patterns for a test suite are assembled. It contains one entry for each pattern that makes up patterns for a test suite. For example for P1 and P2 patterns in Test Suite #1 in Figure 8. Each such entry contains the following information:
 - Unique source file identification
 - Pattern within the source file.
 - Location of the pattern in the list of patterns for the test suite in terms of offset from the last pattern, Start index and optionally the End index.

Figure 8: Simple Test Flow

Test Condition Specification

Test Condition Specification data provides information on the conditions under which the test was performed when the datalog was collected. In particular, conditions that are supported include temperature, timing and voltage. The temperature is a global setting, but the timing and voltage are port-based settings (i.e., one setting per port of the device). The voltage and timing specification is also specific to a test in the test flow.

Validation and Synchronization

Validation and Synchronization data allows the downstream tools to check the fail datalog against any special conditions that are encountered during the execution of the tests during the fail datalog generation. This allows the downstream tools to perform data integrity checks and allows the volume diagnosis flow to remain in sync with respect to the test data, test conditions, fail data collection state and any data transformation/transport. In particular this class of information contains:

- TotalFails: Total number of failures that are logged within the current setup
- BufferLimit[1..N]: This field indicates the fail collection limit per pin.
- FailsAfterBufferFull[1..N]: This is a flag that indicates that failures were observed after the fail buffer became full. One flag per pin is stored. This information allows the diagnosis tools to mark the patterns that were applied after the last pattern/cycle was logged as good/bad, depending on the value of these flags.
- Changelog: If the patterns are modified on the tester after the initial load, then this field will allow communication of those changes to the diagnosis tools. The diagnosis tools can update their image of the patterns to make correct assumptions about the state of those patterns. An example of this is masking of an output, which must be communicated to the downstream tools to not incorrectly assume it to be a passing state
- RunTimeSync: It provides information on status of execution of a test e.g. whether all the information was captured or not w.r.t. a test.

Format Specification

Format specification data indicates the conventions used in the datalog for the fail data. In particular it contains following information:

- Information on the type of datalog. Both cycle based and pattern based datalogs are supported. In addition, the datalog is also used to communicate the pattern change log as well as measured datalog. A flag in the format specification indicates the log type that follows in the datalog.
- Information on how the Z state is handled in the datalog. The Z-handling information allows one to handle a tester's capabilities in terms of making a dual limit comparison.

Fail Data Specification

Fail data specification contains the actual fail log information. Depending on the format being specified in the Format specification, a series of records for the fail log in the

selected format will follow. Depending on the number of failures that are captured, this information will contribute most to the data volume.

Overview of the Standard

As mentioned above, the new standard leverages the existing STDF V4 specifications. The new standard uses the existing records for the device and test equipment identification and adds new record types for the scan test related information. In particular the scan related records are added as the sub-record type under the existing major record types in STDF. Table 1 shows the existing major record types in STDF V4.

Table 1: STDF Major Record Types

Major Type	Description
0*	Information about the STDF file
1*	Data collected on a per lot basis
2	Data collected per wafer
5	Data collected on a per part basis
10	Data collected per test in the test program
15*	Data collected per test execution
20	Data collected per program segment
50	Generic Data

New record sub-types are added under the starred Major types in Table 1. Table 2 shows a structural overview of the standard

Table 2: Structural Overview of the New Standard

Purpose	Records
Version Identification	<div data-bbox="818 432 1260 478" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Version Update Record</div>
Per Lot Information	<div data-bbox="818 537 1260 583" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Pattern Sequence Record</div> <div data-bbox="818 596 1260 642" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Name Map Records</div> <div data-bbox="818 655 1260 701" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Scan Structure Records</div>
Device and Test Setup Information	<div data-bbox="818 737 1260 783" style="border: 1px solid black; background-color: #90EE90; padding: 2px; text-align: center;">Device Identification Records</div> <div data-bbox="818 795 1260 842" style="border: 1px solid black; background-color: #90EE90; padding: 2px; text-align: center;">Test Identification Records</div> <div data-bbox="818 854 1260 900" style="border: 1px solid black; background-color: #90EE90; padding: 2px; text-align: center;">FEH Identification Records</div>
Per Test Execution Information	<div data-bbox="818 961 1260 1100" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Scan Test Record</div> <div data-bbox="1019 1108 1042 1201" style="text-align: center;"> ■ ■ ■ ■ </div> <div data-bbox="818 1220 1260 1358" style="border: 1px solid black; background-color: #ADD8E6; padding: 2px; text-align: center;">Scan Test Record</div>

Use Model

The new standard is meant to coexist with the STDF V4 based data flow. In particular following three use models are supported.

- STDF V4 with no scan fail (existing usage)
- STDF V4 with existing plus the scan fail information
- STDF V4 with Scan fail information only

STDF Record Structure

This section describes the basic STDF record structure. It describes the following general topics, which are applicable to all the record types:

- STDF record header
- Record types and subtypes
- Data type codes and representation
- Optional fields and missing/invalid data

STDF Record Header

Each STDF record begins with a record header consisting of the following three fields:

Field	Field Description
REC_LEN	The number of bytes of data following the record header
REC_TYP	An integer identifying a group of related STDF record types
REC_SUB	An integer identifying a specific STDF record type within each REC_TYP group.

Record Types and Subtypes

The header of each STDF record contains a pair of fields called REC_TYP and REC_SUB. Each REC_TYP value identifies a group of related STDF record types. Each REC_SUB value identifies a single STDF record type within a REC_TYP group. The combination of REC_TYP and REC_SUB values uniquely identifies each record type. This design allows groups of related records to be easily identified by data analysis programs, while providing unique identification for each type of record in the file.

STDF Record Structure

The following table lists the meaning of the REC_TYP codes in STDF V4-2007.

REC_TYP	Code Meaning and STDF REC_SUB Codes
0	Information about the STDF file 10 File Attributes Record (FAR) 20 Audit Trail Record (ATR) 30 Version Update Record (VUR)
1	Data collected on a per lot basis 10 Master Information Record (MIR) 20 Master Results Record (MRR) 30 Part Count Record (PCR) 40 Hardware Bin Record (HBR) 50 Software Bin Record (SBR) 60 Pin Map Record (PMR) 62 Pin Group Record (PGR) 63 Pin List Record (PLR) 70 Retest Data Record (RDR) 80 Site Description Record (SDR) 90 Pattern Sequence Record (PSR) 91 Name Map Record (NMR) 92 Cell Name Record (CNR) 93 Scan Structure Record (SSR) 94 Scan Chain Record (SCR)
2	Data collected per wafer 10 Wafer Information Record (WIR) 20 Wafer Results Record (WRR) 30 Wafer Configuration Record (WCR)
5	Data collected on a per part basis 10 Part Information Record (PIR) 20 Part Results Record (PRR)
10	Data collected per test in the test program 30 Test Synopsis Record (TSR)
15	Data collected per test execution 10 Parametric Test Record (PTR) 15 Multiple-Result Parametric Record (MPR) 20 Functional Test Record (FTR) 30 Scan Test Record (STR)

20	Data collected per program segment 10 Begin Program Section Record (BPS) 20 End Program Section Record (EPS)
<hr/>	
50	Generic Data 10 Generic Data Record (GDR) 30 Datalog Text Record (DTR)
<hr/>	
180	Reserved for use by Image software
<hr/>	
181	Reserved for use by IG900 software

Data Type Codes and Representation

The STDF specification uses a set of data type codes that are concise and easily recognizable. For example, R*4 indicates a REAL (float) value stored in four bytes. A byte consists of eight bits of data. For purposes of this document, the low order bit of each byte is designated as bit 0 and the high order bit as bit 7. The following table gives the complete list of STDF data type codes, as well as the equivalent C language type specifier.

Code	Description	C Type Specifier
C*12	Fixed length character string: If a fixed length character string does not fill the entire field, it must be left-justified and padded with spaces.	char[12]
C*n	Variable length character string: first byte = unsigned count of bytes to follow (maximum of 255 bytes)	char[]
S*n	Variable length character string: first two bytes = unsigned count of bytes to follow (maximum of 65535 bytes)	char[]
C*f	Variable length character string: string length is stored in another field	char[]
U*f	Variable type U type fields where the type f is stored in another field can have value 1,2 or 4	
U*1	One byte unsigned integer	unsigned char
U*2	Two byte unsigned integer	unsigned short
U*4	Four byte unsigned integer	unsigned long
U*8	Eight byte unsigned integer	Unsigned long long
I*1	One byte signed integer	char
I*2	Two byte signed integer	short
I*4	Four byte signed integer	long
R*4	Four byte floating point	float

R*8	Eight byte floating point number	long float (double)
B*6	Fixed length bit-encoded data	char[6]
V*n	Variable data type field: The data type is specified by a code in the first byte, and the data follows (maximum of 255 bytes)	
B*n	Variable length bit-encoded field: First byte = unsigned count of bytes to follow (maximum of 255 bytes). First data item in least significant bit of the second byte of the array (first byte is count.)	char[]
D*n	Variable length bit-encoded field: First two bytes = unsigned count of bits to follow (maximum of 65,535 bits). First data item in least significant bit of the third byte of the array (first two bytes are count). Unused bits at the high order end of the last byte must be zero.	char[]
N*1	Unsigned integer data stored in a nibble. (Nibble = 4 bits of a byte). First item in low 4 bits, second item in high 4 bits. If an odd number of nibbles is indicated, the high nibble of the byte will be zero. Only whole bytes can be written to the STDF file.	char
<i>kxTYPE</i>	Array of data of the type specified. The value of 'k' (the number of elements in the array) is defined in an earlier field in the record. For example, an array of short unsigned integers is defined as <i>kxU*2</i> .	TYPE[]

Optional Fields and Missing/Invalid Data

Certain fields in STDF records are defined as optional. An optional field must be present in the record, but there are ways to indicate that its value is not meaningful, that is, that its data should be considered missing or invalid. STDF V4 – 2007 builds on mechanisms of STDF V4 for missing or invalid fields. It uses the same mechanism as the STDF V4 for indicating missing/invalid data as described below:

- Some optional fields have a predefined value that means that the data for the field is missing. For example, if the optional field is a variable-length character string, a length byte of 0 means that the data is missing. If the field is numeric, a value of -1 may be defined as meaning that the data is missing.
- For other optional fields, all possible stored values, including -1, are legal. In this case, the STDF specification for the record defines an Optional Data bit field. Each bit is used to designate whether an optional field in the record contains valid or invalid data. Usually, if the bit for an optional field is set, any data in the field is invalid and should be ignored.

Data Type	Missing/Invalid Data Flag
Variable-length string	Set the length byte to 0
Fixed-length character string	Fill the field with spaces.
Fixed-length binary string	Set a flag bit in an Optional Data byte.
Time and date fields	Use a binary 0.
Signed and unsigned integers and floating point values	Use the indicated reserved value or set a flag bit in an Optional Data byte.

However for the omission of the optional fields the new standard uses explicit control flags/bits to indicate the absence of optional fields and the first missing optional field does not mean that the rest of the optional fields in the records are missing as well.

Continuation of Records

The amount of data required for some of the new record types will occasionally exceed what can be accommodated in a single 65k record. To facilitate this expanded data volume the concept of “continuation records” is introduced. Any number of continuation records may be added after an initial record type.

The continuation mechanism is implemented by adding a CONT_FLG (B*1) immediately after the Record SubType field. This flag is set to 1 if there are follow on continuation records after the current one. The last record in this sequence of records will have the flag set to 0. In addition for each field that extends over multiple records, a local count is added for that field to indicate the entries that are present in the current record.

STDF Record Types

This section contains the definitions for the STDF record types. The following information is provided for each record type:

- a statement of function: how the record type is used in the STDF file.
- a table defining the data fields: first the standard STDF header, then the fields specific to this record type. The information includes the field name, the data type (see the previous section for the data type codes), a brief description of the field, and the flag to indicate missing or invalid data (see the previous section for a discussion of optional fields).
- any additional notes on specific fields.
- possible uses for this record type in data analysis reports. Note that this entry states only where the record type can be used. It is not a statement that the reports listed always use this record type, even if Teradyne has written those reports. For definitive information on how any data analysis software uses the STDF file, see the documentation for the data analysis software.
- frequency with which the record type appears in the STDF file: for example, once per lot, once per wafer, one per test, and so forth.
- the location of the record type in the STDF file. See the note on “initial sequence”

A note on Initial Record Sequences

For several record types, the “Location” says that the record must appear “after the initial sequence.” The phrase “initial sequence” refers to the records that must appear at the beginning of the STDF file. The requirements for the initial sequence are as follows:

- Every file must contain one File Attributes Record (FAR), one VUR, one Master Information Record (MIR), one or more Part Count Records (PCR), and one Master Results Record (MRR). All other records are optional.
- The first record in the STDF file must be the File Attributes Record (FAR).
- If one or more Audit Trail Records (ATRs) are used, they must appear immediately after the FAR.
- Version Update Record (VUR) which is a required record for STDF V4 – 2007 must appear after the last ATR and before MIR
- The Master Information Record (MIR) must appear in every STDF file. Its location must be after the FAR , ATRs (if ATRs are used) and VUR.
- If the Retest Data Record (RDR) is used, it must appear immediately after the MIR.
- If one or more Site Description Records (SDRs) are used, they must appear immediately after the MIR and RDR (if the RDR is used).

Given these requirements, every STDF V4 2007 must contain one of these initial sequences:

FAR – VUR – MIR
FAR – ATRs – VUR – MIR
FAR – VUR – MIR – RDR
FAR – ATRs – VUR – MIR – RDR
FAR – VUR – MIR – SDRs
FAR – ATRs – VUR – MIR – SDRs
FAR – VUR – MIR – RDR – SDRs
FAR – ATRs – VUR – MIR – RDR – SDRs

All other STDF record types appear after the initial sequence.

Version Update Record (VUR)

Function: Version update Record is used to identify the updates over version V4. Presence of this record indicates that the file may contain records defined by the new standard. This record is added to the major type 0 in the STDF V4.

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (0)	
REC_SUB:	U*1	Record sub-type (30)	
UPD_NAM	C*n	Update Version Name	

Field Description:

UPD_NAM: This field will contain the version update name. For example the new standard name will be stored as “**V4-2007**” string in the UPD_NAM field.

A note on Header Records

STDF V4 -2007 leverages the records from the original STDF V4 specification for the representation of header information related to device identification, Wafer identification and Equipment identification. In particular it uses following records for that purpose:

- Master Information Record (MIR)
- Wafer Information Records (WIR)
- Wafer Result Record (WRR)
- Part Information Record (PIR)
- Part Results Record (PRR)
- Test Synopsis Record (TSR)
- Site Description Record (SDR)

These records are described next where the description has been copied from the original specification for completeness sake. In the description, where the usage of certain fields is modified is highlighted in blue.

Master Information Record (MIR)

Function: The MIR and the MRR (Master Results Record) contain all the global information that is to be stored for a tested lot of parts. Each data stream must have exactly one MIR, immediately after the VUR. This will allow any data reporting or analysis programs access to this information in the shortest possible amount of time.

From the data model perspective it stores following pieces of information:

- Lot ID
- Test Software version
- Test Program version
- Test Flow ID
- Test Stage
- Test Facility ID
- Test Floor ID
- Tester ID

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (1)	
REC_SUB	U*1	Record sub-type (10)	
SETUP_T	U*4	Date and time of job setup	
START_T	U*4	Date and time first part tested	
STAT_NUM	U*1	Tester station number	
MODE_COD	C*1	Test mode code (e.g. prod, dev)	space
RTST_COD	C*1	Lot retest code	space
PROT_COD	C*1	Data protection code	space
BURN_TIM	U*2	Burn-in time (in minutes)	65535
CMOD_COD	C*1	Command mode code	space
LOT_ID	C*n	Lot ID (customer specified)	
PART_TYP	C*n	Part Type (or product ID)	
NODE_NAM	C*n	Name of node that generated data	
TSTR_TYP	C*n	Tester type	
JOB_NAM	C*n	Job name (test program name)	
JOB_REV	C*n	Job (test program) revision number	length byte = 0
SBLOT_ID	C*n	Sublot ID	length byte = 0
OPER_NAM	C*n	Operator name or ID (at setup time)	length byte = 0
EXEC_TYP	C*n	Tester executive software type	length byte = 0
EXEC_VER	C*n	Tester exec software version number	length byte = 0
TEST_COD	C*n	Test phase or step code	length byte = 0
TST_TEMP	C*n	Test temperature	length byte = 0
USER_TXT	C*n	Generic user text	length byte = 0

AUX_FILE	C*n	Name of auxiliary data file	length byte = 0
PKG_TYP	C*n	Package type	length byte = 0
FAMILY_ID	C*n	Product family ID	length byte = 0
DATE_COD	C*n	Date code	length byte = 0
FACIL_ID	C*n	Test facility ID	length byte = 0
FLOOR_ID	C*n	Test floor ID	length byte = 0
PROC_ID	C*n	Fabrication process ID	length byte = 0
OPER_FRQ	C*n	Operation frequency or step	length byte = 0
SPEC_NAM	C*n	Test specification name	length byte = 0
SPEC_VER	C*n	Test specification version number	length byte = 0
FLOW_ID	C*n	Test flow ID	length byte = 0
SETUP_ID	C*n	Test setup ID	length byte = 0
DSGN_REV	C*n	Device design revision	length byte = 0
ENG_ID	C*n	Engineering lot ID	length byte = 0
ROM_COD	C*n	ROM code ID	length byte = 0
SERL_NUM	C*n	Tester serial number	length byte = 0
SUPR_NAM	C*n	Supervisor name or ID	length byte = 0

Field Description:

MODE_COD: Indicates the station mode under which the parts were tested. Currently defined values for the MODE_COD field are:

- A = AEL(Automatic Edge Lock) mode
- C = Checker mode
- D = Development / Debug test mode
- E = Engineering mode (same as Development mode)
- M = Maintenance mode
- P = Production test mode
- Q = Quality Control

All other alphabetic codes are reserved for future use by Teradyne. The characters 0 - 9 are available for customer use.

RTST_COD Indicates whether the lot of parts has been previously tested under the same test conditions. Suggested values are:

- Y = Lot was previously tested.
- N = Lot has not been previously tested.
- space = Not known if lot has been previously tested.
- 0 - 9 = Number of times lot has previously been tested.

PROT_COD User-defined field indicating the protection desired for the test data being stored. Valid values are the ASCII characters 0 - 9 and A - Z. A space in this field indicates a missing value (default protection).

CMOD_COD Indicates the command mode of the tester during testing of the parts. The user or the tester executive software defines command mode values. Valid values are the ASCII characters 0 - 9 and A - Z. A space indicates a missing value.

TEST_COD A user-defined field specifying the phase or step in the device testing process.

TST_TEMP The test temperature is an ASCII string. Therefore, it can be stored as degrees Celsius, Fahrenheit, Kelvin or whatever. It can also be expressed in terms like HOT, ROOM, and COLD if that is preferred.

Wafer Information Record (WIR)

Function: Acts mainly as a marker to indicate where testing of a particular wafer begins for each wafer tested by the job plan. The WIR and the Wafer Results Record (WRR) bracket all the stored information pertaining to one tested wafer. This record is used only when testing at wafer probe. A WIR/WRR pair will have the same HEAD_NUM and SITE_GRP values.

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (2)	
REC_SUB	U*1	Record sub-type (10)	
HEAD_NUM	U*1	Test head number	
SITE_GRP	U*1	Site group number	255
START_T	U*4	Date and time first part tested	
WAFER_ID	C*n	Wafer ID	length byte = 0

Field Description:

SITE_GRP: Refers to the site group in the SDR. This is a means of relating the wafer information to the configuration of the equipment used to test it. If this information is not known, or the tester does not support the concept of site groups, this field should be set to 255.

WAFER_ID: Is optional, but is strongly recommended in order to make the resultant data files as useful as possible.

Wafer Result Record (WRR)

Function: Contains the result information relating to each wafer tested by the job plan. The WRR and the Wafer Information Record (WIR) bracket all the stored information pertaining to one tested wafer. This record is used only when testing at wafer probe time. A WIR/WRR pair will have the same HEAD_NUM and SITE_GRP values.

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (2)	
REC_SUB	U*1	Record sub-type (10)	
HEAD_NUM	U*1	Test head number	
SITE_GRP	U*1	Site group number	255
FINISH_T	U*4	Date and time last part tested	
PART_CNT	U*4	Number of parts Tested	
RTST_CNT	U*4	Number of parts Retested	4,294,967295
ABRT_CNT	U*4	Number of aborts during testing	4,294,967295
GOOD_CNT	U*4	Number of good (passed) parts tested	4,294,967295
FUNC_CNT	U*4	Number of functional parts tested	4,294,967295
WAFER_ID	C*n	Wafer ID	length byte = 0
FABWF_ID	C*n	Fab wafer ID	length byte = 0
FRAME_ID	C*n	Wafer Frame ID	length byte = 0
MASK_ID	C*n	Wafer mask ID	length byte = 0
USR_DESC	C*n	Wafer description supplied by user	length byte = 0
EXC_DESC	C*n	Wafer description supplied by exec	length byte = 0

Field Description:

SITE_GRP: Refers to the site group in the SDR. This is a means of relating the wafer information to the configuration of the equipment used to test it. If this information is not known, or the tester does not support the concept of site groups, this field should be set to 255.

WAFER_ID: Is optional, but is strongly recommended in order to make the resultant data files as useful as possible. A wafer ID in WRR supersedes Wafer ID found in WIR.

FABWF_ID: Is the ID of the wafer when it was in the fabrication process. This facilitates tracking of wafers and correlation of yield with fabrication variations.

FRAME_ID: Facilitates tracking of wafers once the wafer has been through the saw step and the wafer ID is no longer readable on the wafer itself. This is an important piece of information for implementing an inkless binning scheme.

Part Information Record (PIR)

Function: This record acts as a marker to indicate where testing for a particular part begins for each part tested by the test program. The PIR and Part Results Record (PRR) bracket all the stored information pertaining to one tested part.

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (5)	
REC_SUB	U*1	Record sub-type (10)	
HEAD_NUM	U*1	Test head number	
SITE_NUM	U*1	Test site number	

Field Description:

HEAD_NUM, SITE_NUM: If a test system does not support parallel testing, and does not have a standard way to identify its single test site or head, then these fields should be set to 1. When parallel testing, these fields are used to associate individual datalogged results (FTRs and PTRs) with a PIR/PRR pair. An FTR or PTR belongs to the PIR/PRR pair having the same values for HEAD_NUM and SITE_NUM.

Part Results Record (PRR)

Function: This record is used to identify the part for which datalog is generated. It is used in conjunction with MIR and WIR to uniquely identify the part. In particular following data model objects are stored in this record.

- XCOORD, YCOORD
- Electronic ID (Stored in PART_TXT)
- Sr. No (Stored in PART_ID)

The PRR and the Part Information Record (PIR) bracket all the stored information pertaining to one tested part

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (5)	
REC_SUB	U*1	Record sub-type (20)	
HEAD_NUM	U*1	Test head number	
SITE_NUM	U*1	Test site number	
PART_FLG	B*1	Part information flag	
NUM_TEST	U*2	Number of tests executed	
HARD_BIN	U*2	Hardware bin number	
SOFT_BIN	U*2	Software bin number	65535
X_COORD	I*2	(Wafer) X coordinate	-32768
Y_COORD	I*2	(Wafer) Y coordinate	-32768
TEST_T	U*4	Elapsed test time in milliseconds	0
PART_ID	C*n	Part identification	length byte = 0
PART_TXT	C*n	Part description text	length byte = 0
PART_FIX	B*n	Part repair information	length byte = 0

Field Description:

HEAD_NUM,SITE_NUM: If a test system does not support parallel testing, and does not have a standard way to identify its single test site or head, then these fields should be set to 1. When parallel testing, these fields are used to associate individual datalogged results(FTRs and PTRs) with a PIR/PRR pair. An FTR or PTR belongs to the PIR/PRR pair having the same values for HEAD_NUM and SITE_NUM.

X_COORD,Y_COORD: Have legal values in the range -32767 to 32767. A missing value is indicated by the value -32768.

X_COORD,Y_COORD, PART_ID are all optional, but you should provide either the PART_ID or the X_COORD and Y_COORD in order to make the resultant data useful for analysis.

PART_FLG: Contains the following fields:

- bit 0: 0 = This is a new part. Its data device does not supersede that of any previous device.
1 = The PIR, PTR, MPR, FTR, and PRR records that make up the current sequence (identified as having the same HEAD_NUM and SITE_NUM) supersede any previous sequence of records with the same PART_ID. (A repeated part sequence usually indicates a mistested part.)
- bit 1: 0 = This is a new part. Its data device does not supersede that of any previous device.
1 = The PIR, PTR, MPR, FTR, and PRR records that make up the current sequence (identified as having the same HEAD_NUM and SITE_NUM) supersede any previous sequence of records with the same X_COORD and Y_COORD. (A repeated part sequence usually indicates a mistested part.) **Note:** Either Bit 0 or Bit 1 can be set, but **not both**. (It is also valid to have neither set.)
- bit 2: 0 = Part testing completed normally
1 = Abnormal end of testing
- bit 3: 0 = Part passed
1 = Part failed
- bit 4: 0 = Pass/fail flag (bit 3) is valid
1 = Device completed testing with no pass/fail indication (i.e., bit 3 is invalid)
- bits 5 - 7: Reserved for future use — must be 0

HARD_BIN: Has legal values in the range 0 to 32767.

SOFT_BIN: Has legal values in the range 0 to 32767. A missing value is indicated by the value 65535.

PART_FIX: This is an application-specific field for storing device repair information. It may be used for bit-encoded, integer, floating point, or character information. Regardless of the information stored, the first byte must contain the number of bytes to follow. This field can be decoded only by an application-specific analysis program.

PART_TXT: This field is used store any text description of the part. This field will be used also for storing the Electronic ID in this standard. Electronic ID will be stored in ASCII form at the end of the existing part description and will be separated by a colon. It is optional to store the Electronic ID, in that case the PART_TXT will be used in the same way as in STDF V4.

PART_ID: This field is used to store part identification in ASCII form. The same field will be used to store the Sr. No. It will be added at the end of existing PART_ID string and will be separated by a colon. It is optional to add the part identification in that case, the PSRT_ID will be used as before in STDF V4.

Test Synopsis Record (TSR)

Function: Contains the test execution and failure counts for one parametric, functional, or scan test in the test program. Also contains static information, such as test name. The TSR is related to the Functional Test Record (FTR), the Parametric Test Record (PTR), the Multiple Parametric Test Record (MPR), and the Scan Test Record (STR) by test number, head number, and site number.

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (10)	
REC_SUB	U*1	Record sub-type (30)	
HEAD_NUM	U*1	Test head number See note	
SITE_NUM	U*1	Test site number	
TEST_TYP	C*1	Test type space	
TEST_NUM	U*4	Test number	
EXEC_CNT	U*4	Number of test executions	4,294,967,295
FAIL_CNT	U*4	Number of test failures	4,294,967,295
ALRM_CNT	U*4	Number of alarmed tests	4,294,967,295
TEST_NAM	C*n	Test name	length byte = 0
SEQ_NAME	C*n	Sequencer(program segment/flow) name	length byte = 0
TEST_LBL	C*n	Test label or text	length byte = 0
OPT_FLAG	B*1	Optional data flag See note	
TEST_TIM	R*4	Average test execution time in seconds	OPT_FLAG bit2= 1
TEST_MIN	R*4	Lowest test result value	OPT_FLAG bit0= 1
TEST_MAX	R*4	Highest test result value	OPT_FLAG bit1= 1
TST_SUMS	R*4	Sum of test result values	OPT_FLAG bit4= 1
TST_SQRS	R*4	Sum of squares of test result values	OPT_FLAG bit5= 1

Field Description:

HEAD_NUM: If this TSR contains a summary of the test counts for all test sites, this field must be set to 255.

TEST_TYP: Indicates what type of test this summary data is for. Valid values are:

- P = Parametric test
- F = Functional test
- M = Multiple-result parametric test
- S = Scan Test
- space = Unknown

EXEC_CNT,FAIL_CNT,ALRM_CNT: Are optional, but are strongly recommended because they are needed to compute values for complete final summary sheets.

OPT_FLAG: Contains the following fields:

bit 0 set = TEST_MIN value is invalid

bit 1 set = TEST_MAX value is invalid

bit 2 set = TEST_TIM value is invalid

bit 3 is reserved for future use and must be 1

bit 4 set = TST_SUMS value is invalid

bit 5 set = TST_SQRS value is invalid

bits 6 - 7 are reserved for future use and must be 1

OPT_FLAG is optional if it is the last field in the record.

TST_SUMS,TST_SQRS: Are useful in calculating the mean and standard deviation for a single lot or when combining test data from multiple STDF files

Site Description Record (SDR)

Function: This record is used to identify the equipment in the test cell where the part was tested and contains the configuration information for one or more test sites, connected to one testhead, that compose a site group. Following data model objects are stored in this record:

- Prober ID (HAND_ID)
- Probe Card ID (CARD_ID)
- Handler ID (HAND_ID)
- Loadboard ID (In LOAD_ID)

Data Fields:

Field Name	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN	U*2	Bytes of data following header	
REC_TYP	U*1	Record type (1)	
REC_SUB	U*1	Record sub-type (80)	
HEAD_NUM	U*1	Test head number	
SITE_GRP	U*1	Site group number	
SITE_CNT	U*1	Number (<i>k</i>) of test sites in site group	
SITE_NUM	kxU*1	Array of test site numbers	
HAND_TYP	C*n	Handler or prober type	length byte = 0
HAND_ID	C*n	Handler or prober ID	length byte = 0
CARD_TYP	C*n	Probe card type	length byte = 0
CARD_ID	C*n	Probe card ID	length byte = 0
LOAD_TYP	C*n	Load board type	length byte = 0
LOAD_ID	C*n	Load board ID	length byte = 0
DIB_TYP	C*n	DIB board type	length byte = 0
DIB_ID	C*n	DIB board ID	length byte = 0
CABL_TYP	C*n	Interface cable type	length byte = 0
CABL_ID	C*n	Interface cable ID	length byte = 0
CONT_TYP	C*n	Handler contactor type	length byte = 0
CONT_ID	C*n	Handler contactor ID	length byte = 0
LASR_TYP	C*n	Laser type	length byte = 0
LASR_ID	C*n	Laser ID	length byte = 0
EXTR_TYP	C*n	Extra equipment type field	length byte = 0
EXTR_ID	C*n	Extra equipment ID	length byte = 0

Field Description:

SITE_GRP Specifies a site group number (called a station number on some testers) for the group of sites whose configuration is defined by this record. Note that this is different from the station number specified in the MIR, which refers to a software station only. The value in this field must be unique within the STDF file.

SITE_CNT, SITE_NUM, SITE_CNT tells how many sites are in the site group that the current SDR configuration applies to. **SITE_NUM** is an array of those site numbers.

_TYP fields These are the type or model number of the interface or peripheral equipment being used for testing:

**HAND_TYP, CARD_TYP, LOAD_TYP, DIB_TYP,
CABL_TYP, CONT_TYP, LASR_TYP, EXTR_TYP**

_ID fields These are the IDs or serial numbers of the interface or peripheral equipment being used for testing:

**HAND_ID, CARD_ID, LOAD_ID, DIB_ID,
CABL_ID, CONT_ID, LASR_ID, EXTR_ID**

Pattern Sequence Record (PSR)

Function: PSR record contains the information on the pattern profile for a specific executed scan test as part of the Test Identification information. In particular it implements the Test Pattern Map data object in the data model. It specifies how the patterns for that test were constructed. There will be a PSR record for each scan test in a test program. A PSR is referenced by the STR (Scan Test Record) using its PSR_INDX field

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (1)	
REC_SUB:	U*1	Record sub-type (90)	
CONT_FLG	B*1	Continuation PSR record exist; default 0	
PSR_INDX	U*2	PSR Record Index (used by STR records)	
PSR_NAM	C*n	Symbolic name of PSR record	length byte = 0
OPT_FLG	B*1	Contains PAT_LBL, FILE_UID, ATPG_DSC, and SRC_ID field missing flag bits and flag for start index for first cycle number.	
TOTP_CNT	U*2	Count of total pattern file information sets in the complete PSR data set	
LOCP_CNT	U*2	Count (k) of pattern file information sets in this record	
PAT_BGN	kxU*8	Array of Cycle #'s patterns begins on	
PAT_END	kxU*8	Array of Cycle #'s patterns stops at	
PAT_FILE	kxC*n	Array of Pattern File Names	
PAT_LBL	K*C*n	Optional pattern symbolic name	OPT_FLG bit 0 = 1
FILE_UID	kxC*n	Optional array of file identifier code	OPT_FLG bit 1 = 1
ATPG_DSC	kxC*n	Optional array of ATPG information	OPT_FLG bit 2 = 1
SRC_ID	kxC*n	Optional array of PatternInSrcFileID	OPT_FLG bit 3 = 1

Field Description:

CONT_FLG: This flag is used to indicated existence of continuation PSR records. If it is set to 1 then it mean a continuation PSR exists. A 0 value indicated that this is the last PSR record.

PSR_INDX: This is a unique identifier for the set of PSRs that describe the patterns for a scan test.

PSR_NAM: It is a symbolic name of the test suite to which this PSR belongs. For example with reference to figure 8, it would be stuck-at for the test_suite #1.

OPT_FLG: This flag is used to indicate the presence of optional fields. The bit assignment for the optional fields is as shown in Table 3. If the bit is set to 1 the corresponding optional field is considered missing

Table 3: Optional Field Flags in PSR

Bit	Description
0	Symbolic pattern label missing
1	Unique File Identifier for the file is missing
2	Details of ATPG used to create the patterns
3	Identification of a pattern within a source file
4	The first cycle number is determined by the value of this bit.
5	The first pattern number is determined by the value of this bit.
6	The bit position starts with the value of this bit

TOTP_CNT: This field indicates the total number of patterns that make up a scan test over all the PSRs. The description of all the patterns may not fit into a single PSR as mentioned above. For continuation records this should be the same count as for the first record (i.e. the final total)

LOCP_CNT: This field indicates the total number of patterns that are described in the current PSR from a scan test.

NOTE 1 The next set of fields is repeated for each pattern that is contained in a scan test. Each of these fields is stored in its own array of size LOCAL_CNT.

PAT_FILE : The name of the ATPG file from which the current pattern was created

PAT_BGN: The cycle count the specified ATPG pattern begins on. The 1st cycle number is determined by the OPT_FLG (bit 4).

PAT_END : The cycle count the specified ATPG pattern ends on.

PAT_LBL: (Optional) This is a symbolic name of the pattern within a test suite. For example, with reference to figure 8 it will be P1 for the pattern coming from file1.

FILE_UID: (Optional) - Unique character string that uniquely identifies the file. This field is provided as a means to additionally uniquely identify the source file. The exact mechanism to use this field is decided by the ATPG software, which will also provide this piece of information in the source files during the translation process.

SRC_ID: (Optional) - The name of the specific PatternExec block in the source file. In case there are multiple patterns being specified in the source file e.g. multiple PatternExec blocks in STIL, this field specifies the one, which is the source of the pattern in this PSR

ATPG_DSC (Optional) – This field intended to be used to store any ASCII data that can identify the source tool, time of generation etc.

Scan Test Record (STR)

Function: Scan Test Record (STR) is a new record that is added to the major record type 15 category (Data Collected Per Test Execution). This is the same category where functional and parametric fail records exist. Thus the scan test record becomes another test record type in this category.

It contains all or some of the results of the single execution of a scan test in the test program. It is intended to contain all of the individual pin/cycle failures that are detected in a single test execution. If there are more failures than can be contained in a single record, then the record may be followed by additional continuation STR records.

In this new record some fields have been brought over from the functional test record and some new fields have been added to handle the scan test data. Table 4 shows the structure of the STR at a conceptual level.

Table 4: STR Record Structure

Class of Information	Information Fields
Continuation Fields	(X of Y)
Flags for Optional Fields	FAL Flag, Mask Map Flag
Test Setup Information	Test No, Test Head Number, Test Site, Test Flags Etc (Brought over from FTR)
Validation and Synchronization Information	Buffer fail status, Global Mask Status, Fail limit Info,
Test Condition Specification with Optional Fields Specification	Scan_Freq, Capture Frequency, Voltage, Optional
Datalog Format Specification	Z-handling, Data Field Map
Datalog with Per fail optional Fields	Pin Info, Pattern/Cycle no/FF Name, Measured Data, Expected data, Fail data, optional data

The fields in the STR records correspond to various categories of table 4. Table below shows the details of an STR record. The description of the STR fields is classified according to those categories in Table 4.

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (15)	
REC_SUB:	U*1	Record sub-type (30)	
CONT_FLG	B*1	Continuation STR follows if not 0	
TEST_NUM	U*4	Test number	
HEAD_NUM	U*1	Test head number	
SITE_NUM	U*1	Test site number	
PSR_REF	U*2	PSR Index (Pattern Sequence Record)	
TEST_FLG	B*1	Test flags (fail, alarm, etc.)	
LOG_TYP	C*n	User defined description of datalog	length byte = 0
TEST_TXT	C*n	Descriptive text or label	length byte = 0
ALARM_ID	C*n	Name of alarm	length byte = 0
PROG_TXT	C*n	Additional Programmed information	length byte = 0
RSLT_TXT	C*n	Additional result information	length byte = 0
Z_VAL	U*1	Z Handling Flag	
FMU_FLG	B*1	MASK_MAP & FAL_MAP field status & Pattern Changed flag	
MASK_MAP	D*n	Bit map of Globally Masked Pins	FMU_FLG bit 0 = 0 OR bit1 = 1
FAL_MAP	D*n	Bit map of failures after buffer full	FMU_FLG bit 2 = 0 OR bit3 = 1
CYC_CNT	U*8	Total cycles executed in test	
TOTF_CNT	U*4	Total failures (pin x cycle) detected in test execution	
TOTL_CNT	U*4	Total fails logged across the complete STR data set	
CYC_BASE	U*8	Cycle offset to apply for the values in the CYCL_NUM array	
BIT_BASE	U*4	Offset to apply for the values in the BIT_POS array	
COND_CNT	U*2	Count (g) of Test Conditions and optional data specifications in present record	
LIM_CNT	U*2	Count (j) of LIM Arrays in present record, 1 for global specification	
CYC_SIZE	U*1	Size (f) of data (1,2,4, or 8 bytes) in CYC_OFST field	0

PMR_SIZE	U*1	Size (f) of data (1 or 2 bytes) in PMR_INDX field	0
CHN_SIZE	U*1	Size (f) of data (1, 2 or 4 bytes) in CHN_NUM field	0
PAT_SIZE	U*1	Size (f) of data (1,2, or 4 bytes) in PAT_NUM field	0
BIT_SIZE	U*1	Size (f) of data (1,2, or 4 bytes) in BIT_POS field	0
U1_SIZE	U*1	Size (f) of data (1,2,4 or 8 bytes) in USR1 field	0
U2_SIZE	U*1	Size (f) of data (1,2,4 or 8 bytes) in USR2 field	0
U3_SIZE	U*1	Size (f) of data (1,2,4 or 8 bytes) in USR3 field	0
UTX_SIZE	U*1	Size (f) of each string entry in USER_TXT array	0
CAP_BGN	U*2	Offset added to BIT_POS value to indicate capture cycles	
LIM_INDX	jxU*2	Array of PMR indexes that require unique limit specifications	LIM_CNT=0
LIM_SPEC	jxU*4	Array of fail datalogging limits for the PMRs listed in LIM_INDX	LIM_CNT=0
COND_LST	gxU*n	Array of test condition (Name=value) pairs	COND_CNT=0
CYC_CNT	U*2	Count (k) of entries in CYC_OFST array	0
CYC_OFST	kxU*f	Array of cycle numbers relative to CYC_BASE	CYC_CNT = 0
PMR_CNT	U*2	Count (k) of entries in the PMR_INDX array	0
PMR_INDX	kxU*f	Array of PMR Indexes (All Formats)	PMR_CNT=0
CHN_CNT	U*2	Count (k) of entries in the CHN_NUM array	0
CHN_NUM	kxU*f	Array of Chain No for FF Name Mapping	CHN_CNT=0
EXP_CNT	U*2	Count (k) of EXP_DATA array entries	0
EXP_DATA	mxU*1	Array of expected vector data	EXP_CNT=0
CAP_CNT	U*2	Count (k) of CAP_DATA array entries	0
CAP_DATA	kxU*1	Array of captured data	CAP_CNT=0
NEW_CNT	U*2	Count (k) of NEW_DATA array entries	0
NEW_DATA	kxU*1	Array of new vector data	NEW_CNT=0
PAT_CNT	U*2	Count (k) of PAT_NUM array entries	0
PAT_NUM	kxU*f	Array of pattern # (Ptn/Chn/Bit format)	PAT_CNT=0

BPOS_CNT	U*2	Count (k) of BIT_POS array entries	0
BIT_POS	kxU*f	Array of chain bit positions (Ptn/Chn/Bit format)	BPOS_CNT=0
USR1_CNT	U*2	Count (k) of USR1 array entries	0
USR1	kxU*f	Array of user defined data for each logged fail	USR1_CNT= 0;
USR2_CNT	U*2	Count (k) of USR2 array entries	0
USR2	kxU*f	Array of user defined data for each logged fail	USR2_CNT= 0;
USR3_CNT	U*2	Count (k) of USR3 array entries	0
USR3	kxU*f	Array of user defined data for each logged fail	USR3_CNT= 0;
TXT_CNT	U*2	Count (k) of USER_TXT array entries	0
USER_TXT	kxC*f	Array of user defined fixed length strings for each logged fail	TXT_CNT = 0

Field Description:

TEST_NUM: It is the identifier for the test for which data is collected. It should be populated with the Test Number.

HEAD_NUM,SITE_NUM: If a test system does not support parallel testing, and does not have a standard way of identifying its single test site or head, these fields should be set to 1. When parallel testing, these fields are used to associate individual datalogged results with a PIR/PRR pair. An FTR belongs to the PIR/PRR pair having the same values for HEAD_NUM and SITE_NUM.

TEST_FLG Contains the following fields:

- bit 0: 0 = No alarm
1 = Alarm detected
- bit 1: Reserved for future
- bit 2: 0 = Test result is reliable
1 = Test result is unreliable
- bit 3: 0 = No timeout
1 = Timeout occurred
- bit 4: 0 = Test was executed
1 = Test not executed
- bit 5: 0 = No abort
1 = Test aborted
- bit 6: 0 = Pass/fail flag
1 = Test completed
- bit 7: 0 = Test passed
1 = Test failed

LOG_TYP: This is a user defined description of the datalog type to indicate what type of information is stored in the current record.

TEST_TXT: This is a user given description name of the test

ALARM_ID If the alarm flag (bit 0 of TEST_FLG) is set, this field can optionally contain the name or ID of the alarm or alarms that were triggered. The names of these alarms are tester-dependent.

PROG_TXT: This is also a user provided information. Any additional information regarding programming can be provided.

RSLT_TXT: This is also a user provided information. Any additional information about the results can be provided

PSR_REF: This is the reference to PSR(s) that describes the patterns for the test for which the data log is stored in the current STR. In case the patterns are described by multiple continuation PSRs then the reference would contain the index of the first PSR.

Z_VAL: This is the flag to indicate the how the Z (Dual side comparison) values were handled on the ATE. Table 5 shows the modes that are supported. The first entry is for the ATE that doesn't perform dual side comparison. While the rest of the entries are to be used by the ATE that can and in that case it is meant to communicate how the Z-character was mapped in the datalog. Enumeration value '3' (Z mapped to Z) means that a compare to mid-level (between L and H state) is done for 'expected Z' in the patterns. This typically requires a dual-threshold comparator combined with an active load circuit on the ATE side, to pull the device output signals to mid-level when its output drivers are tristated.

Table 5: Z Handling Flags

Enumeration value	condition
0	Not handled
1	Z mapped to L
2	Z mapped to H
3	Z mapped to Z
4	Z mapped to X

FMU_FLG: This field describes the status of the fails after logging, Mask Map fields in STR as well as the flag to indicate pattern modified flag. Bits 0 and 1 indicate the status of the FAL_MAP and the Bit 2 and 3 described the status of Mask map. Table 6 shows the modes of the FAL_MAP and Table 7 shows the modes for Mask map

Table 6: FAL MAP Flag Description

FMU_FLG:bit 2	FMU_FLG:bit 3	Description
0	0	No information of buffer status is provided
0	1	All fails were logged, FAL_MAP not present
1	0	FAL_MAP present
1	1	Unused

Table 7: Mask Map Flag Description

FMU_FLG:bit 0	FMU_FLG:bit 1	Description
0	0	Mask map not present; No pin is globally masked
0	1	Use the previous MASK_MAP definition (MASK_MAP in the current record absent)
1	0	Use the MASK_MAP in the current record and make it persistent
1	1	Unused

Bit 4 is used to indicate if the patterns on the ATE have been modified compared to the previous image. If bit 4 is set to 1 then indicates that patterns have been modified and a 0 means no change

MASK_MAP: This optional field contains an array of bits corresponding to the PMR index numbers of the comparators that were disabled during the test. The 1st bit corresponds to PMR index 1, the second bit corresponds to PMR index 2 and so on. Each comparator that is disabled will have its corresponding PMR index bit set to 1. (Note that this field applies to the present record only plus any following continuation STR records). If this field is missing, then it is assumed that conventional pin enabling as defined in the source pattern source file specified in the referenced PSR records apply. The MASK_MAP fields are controlled by the Mask Map Fail bits in FMU_FLG and the behavior is described in Table 7

FAL_MAP (Failures After Logging Map): : This is an optional field that contains an array of bits corresponding to the PMR index numbers of the pins that had any failure after the fail data logging was stopped during the test. The 1st bit corresponds to PMR index 1, the second bit corresponds to PMR index 2 and so on. Each pin that has at least one failure will have its corresponding PMR index bit set to 1. (Note that this field applies to the present record only plus any following continuation STR records). If this field is missing, then it is assumed that conventional pin enabling as defined in the source pattern source file specified in the referenced PSR records apply. The FAL_MAP field is controlled by the FAL map bits in FMU_FLG and the behavior is described in Table 6.

Validation and Synchronization Fields

CYC_CNT: The total number of cycles that were executed in this test. If 0 then it should be inferred that this value was not determinable

TOTF_CNT: The total number of failures that were detected in this test, logged or not. A failure is defined as a pin and cycle, such as in three pins failed in the same cycle, that would be counted as 3 failures. If 0 then it should be inferred that this value was not determinable

TOTL_CNT: The total number of failures that were detected and logged in this test. A failure is defined as a pin and cycle, such as in three pins failed in the same cycle, that would be counted as 3 failures. This count includes the total failures from the test execution and includes any following continuation STR records.

CYC_BASE: This field is of type U*8 and contains the offset for the cycle numbers in the fail log. This mechanism allows only U*4 values for the cycle numbers in the fail log (vs. U*8) and thus reduces the data volume. The actual cycle number for the fail log entries would be $CYC_BASE + \langle \text{fail Cycle No in the log} \rangle$. The cycle numbers are the ATPG cycle numbers i.e. in case of multiple ATPG cycles being represented in a tester cycle the tester cycle numbers will have to be decoded into ATPG cycles.

BIT_BASE: This field is of type U*2 and contains the offset for the bit positions in the fail log for the capture cycles in the pattern/chain/bit format. Please note that in the pattern/chain/bit format the BIT_POS does not correspond to any scan chain position during the capture cycles. Therefore a separate number space is created for the BIT_POS values during the capture cycles to avoid confusion with the valid BIT_POS across all the scan chains.

LIM_CNT: This field specifies the number of pins for which the fail datalog limits specification is provided in the record.

CYC_SIZE: This field specifies the data size (1, 2, 4, or 8 bytes) of each entry in the CYC_OFST array field.

PMR_SIZE: This field specifies the data size (1 or 2 bytes) of each entry in the PMR_INDX array field.

CHN_SIZE: This field specifies the data size (1, 2, or 4 bytes) of each entry in the CHN_NUM array field.

PAT_SIZE: This field specifies the data size (1, 2, or 4 bytes) of each entry in the PAT_NUM array.

BIT_SIZE: This field specifies the data size (1, 2, or 4 bytes) of each entry in the BIT_POS array.

U1_SIZE, U2_SIZE, U3_SIZE: These fields specify the data size (1, 2, 4, or 8 bytes) of each entries in USR1, USR2 and USR3 arrays respectively.

CAP_BGN: When logging failures in the PAT_NUM and BIT_POS fields, and the failures occur on cycles during the “capture” interval between scan patterns, a means to clearly identify these cycles need to be conveyed. To facilitate this, the CAP_BGN field specifies a value (which must be larger than the largest scan chain bit position) which references the first capture cycle after a scan pattern. For example, if the max scan chain pattern length is 1025, the CAP_BGN can be arbitrarily set to a value of “2000” (any arbitrary value greater than 1025). Thus the reader would relate the value “2000” in the BIT_POS array to indicate a failure on the 1st capture cycle, “2001” the 2nd capture cycle, etc

LIM_INDX: This is an array which contains the PMR indexes of the pins for which the fail logging limits is provided. Please note that the first location in this array is location 0 and is reserved for indicating all pins or default pins. The number of entries in this array is specified by the LIM_CNT described above.

LIM_SPEC: This array contains the fail log limits for the pins which are listed in the LIM_INDX array. The first location in this array specifies the value that is the default value that is applied to all the pins for which an explicit limit is not specified in this array. Thus in global case where a single limit applied to all the pins, this array contains only one element the element at location 0. The number of entries in this array is specified by the LIM_CNT described above.

Test Condition Specification

Test conditions are specified using an array of strings in the COND_LST field array. Each condition is represented as “condition=value” in ASCII without the quotes. Each condition specification is stored in a separate entry in the COND_LST array. The size of this array (or the number of conditions specified) is specified by the COND_CNT field.

The standard reserves the following two keywords for condition names.

- SHIFT_FREQ: The shift frequency for the scan test.
- CAPTURE_FREQ: The capture frequency for the scan test.

A user can add other environment specific conditions using this field by adding their custom condition names and values to this array e.g. CORE_ID=<core-id-name>.

There is one exception to the test condition specification and that is Temperature specification. Since, the temperature is more of a global test condition and a field exists in the Master Information Record (MIR) to represent that, the temperature does not need to be present in the STR. The standard however does not preclude one from putting another temperature parameter in the test conditions array mentioned above

Datalog

The fail datalog section of the STR record is organized as a super record which can support recorded failures in each of the data field arrays described below. Each of these field arrays is optional as determined by their corresponding “Count” field.

CYC_CNT: This field specifies the number of entries in the CYC_OFST field.

CYC_OFST: An array of cycle numbers that correspond to the ATE cycles # at which the failure occurred. The size of each entry (1, 2, 4, or 8 bytes) is specified in the CYC_SIZE field.. The first cycle executed in a test (‘0’ or ‘1’) is specified in the OPT_FLG (bit 3) field of the PSR record specified in the PSR_REF field. Note that the CYC_OFST values are also relative to the value specified in CYC_BASE field described earlier, and the actual cycle for the fail log entries would be CYC_BASE + <fail Cycle No in the log>. The number of entries in this array is specified in the CYC_CNT field.

PMR_CNT: This field specifies the number of entries in the PMR_INDX field.

PMR_INDX: An array of PMR indexes that correspond either to the CYC_NUM array or to the PAT_NUM array. The size of each entry (1 or 2 bytes) is specified in the PMR_SIZE field. The number of entries in the array is specified in the PMR_CNT field.

CHN_CNT: This field specifies the number of entries in the CHN_NUM field.

CHN_NUM: An array of scan chain numbers at which the failure was observed. The size of each entry (1 or 2 bytes) in the array is specified in the CHN_SIZE field. The number of entries in the array is specified in the CHN_CNT field. The primary purpose of this field is to support pattern/chain/bit based logging (when used with the PAT_NUM and BIT_POS arrays). In addition, this field, along with the BIT_POS, can be used to identify the CNR record (described later) that contains the scan cell name corresponding to this CHN_NUM and BIT_POS. The first bit position # (0 or 1) is specified in the referenced PSR record's OPT_FLG field (bit 5).

CAP_CNT: It contains the number of entries in the CAP_DATA.

CAP_DATA: An array of 1 byte characters that correspond to the CYC_OFST ("Cycle mode") or PAT_NUM ("Pattern Mode") entries that indicate the "captured" data state. This function is generally the same as the EXP_DATA array except is intended to infer that this data does not represent a failure, but rather the data states "captured" by the tester, e.g. in a scan data dump application. The number of entries in the array is specified in the CAP_CNT field.

EXP_CNT: It contains the number of entries in the EXP_DATA.

EXP_DATA: An array of 1 byte characters that correspond to the CYC_OFST ("Cycle mode") or PAT_NUM ("Pattern Mode") entries that indicate the data state that was specified in the source pattern file for this specific pin and Cycle or Pattern/Bit. The size of this array is specified in the EXP_CNT field. This data field has multiple applications:

1. Can be used when it is required to provide the expect data associated with each failure. This can be used to provide validation (when required) of the expected data for a cycle # on the ATE to the expected data in the source pattern file (as a note: Generally only a few initial representative cycles would be required for this function, and only once in an STDF file for each specific PSR utilization.)
2. Can also be used to represent the "Old" data states when used in conjunction with the following "NEW_DATA array when transmitting an STR record for the purposes of defining test pattern modifications

NEW_CNT: This field specifies the number of entries in the NEW_DATA field.

NEW_DATA: An array of 1 byte characters that correspond to the CYC_OFST ("Cycle mode") or PAT_NUM ("Pattern Mode") entries that indicate any test pattern data modifications made to the original data in the source patterns. The # of entries in the array is specified in the NEW_CNT field.

PAT_CNT: This field specifies the number of entries in the PAT_NUM field..

PAT_NUM: When used in the "Pattern" format, an array of integers specifying the failing pattern number. The first pattern # (0 or 1) is specified in the referenced PSR record's OPT_FLG field (bit 4). The number of bytes of each entry is specified in the

PAT_SIZE field (1, 2, or 4 bytes). The number of entries in this array is specified in the PAT_CNT field.

BPOS_CNT: This field specifies the number of entries in the BIT_POS field.

BIT_POS: When used in the "Pattern" format, an array of integers specifying the bit position in the scan chain. The number of bytes per entry (1, 2, or 4 bytes) is specified in the BIT_SIZE field. This field can also be used in conjunction with the CHN_NUM field to support the applications where Flip Flop name needs to be derived from a SSR record. The CHN_NUM and BIT_POS together will be used as an index in the SSR table for getting the Flip Flop name in that case. The number of entries in the array is specified in the BPOS_CNT field. The first bit position # (0 or 1) is specified in the referenced PSR record's OPT_FLG field (bit 6).

USR1_CNT, USR2_CNT, USR3_CNT: These fields specify the number of entries in the USR1 USR2, USR3 arrays respectively.

USR1, USR2, USR3: These are optional user defined fields. The number of bytes per entry (1, 2, 4, or 8 bytes) is specified by the corresponding U1_SIZE, R2_SIZE and U3_SIZE fields as mentioned earlier. The number of entries of each array is specified respectfully in the USR1_CNT, USR2_CNT, and USR3_CNT fields.

TXT_CNT: contains the number of entries in the USER_TXT array.

USER_TXT: This is an optional array of fixed length text strings. The length (# of characters) of each entry is specified by the UTX_SIZE field. The # of entries in the array is specified in the TXT_CNT field.

Name Map Record (NMR)

Function: This record contains a map of PMR indexes to ATPG signal names. This record is designed to allow preservation of ATPG signal names used in the ATPG files through the datalog output. This record is only required when the standard PMR records do not contain the ATPG signal name

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (1)	
REC_SUB:	U*1	Record sub-type (91)	
CONT_FLG	B*1	Continuation NMR record follows if not 0	
TOTM_CNT	U*2	Count of PMR indexes and ATPG_NAM entries	0
LOCM_CNT	U*2	Count of (k) PMR indexes and ATPG_NAM entries in this record	0
PMR_INDX	kxU*2	Array of PMR indexes	LOCM_CNT=0
ATPG_NAM	kxC*n	Array of ATPG signal names	LOCM_CNT=0

TOTM_CNT: This the count of total number of entries in the mapping table across all the NMR records

LOCM_CNT: The count of number of entries in the current NMR record.

PMR_INDX: It is the array of PMR indexes for which the ATPG names are provided

ATPG_NAM: It is the array ATPG signal names corresponding to the pin in PMR_INDX array.

Scan Cell Name Record (CNR)

Function: This record is used to store the mapping from Chain and Bit position to the Cell/FlipFlop name. A CNR record should be created for each Cell for which a name mapping is required. Typical usage would be to create a record for each failing cell/FlipFlop. A CNR with new mapping for a chain and bit position would override the previous mapping.

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (1)	
REC_SUB:	U*1	Record sub-type (92)	
CHN_NUM	U*2	Chain number. Referenced by the CHN_NUM array in an STR record	
BIT_POS	U*4	Bit position in the chain	
CELL_NAM	S*n	Scan Cell Name	

Field Description:

CHN_NUM: This is the array for the chain identification for the target Flip Flop for which the name is provided in the table.

BIT_POS: This is an array for the bit position within the chain identified by the CHAIN_NO field for the target Flip Flop for which the name is provided in the table.

CELL_NAM: This is the name of the Flip Flop at the CHN_NUM and BIT_POS. Please note the type of this field is S*n where the length of the Flip Flop name is stored in the first two bytes and then the name follows.

Scan Structure Record (SSR)

Function: This record contains the Scan Structure information normally found in a STIL file. The SSR is a top level Scan Structure record that contains an array of indexes to CDR (Chain Description Record) records which contain the chain information.

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (1)	
REC_SUB:	U*1	Record sub-type (93)	
SSR_NAM	C*n	Name of the STIL Scan Structure for reference	Length byte = 0
CHN_CNT	U*2	Count (k) of number of Chains listed in CHN_LIST	
CHN_LIST	kxU*2	Array of CDR Indexes	

Field Descriptions:

SSR_NAM: This is a ASCII unique name for the scan structure record that is normally provided by the STIL (**IEEE 1450**) file.

CHN_CNT: It is the count of number of scan chains in a scan structure.

CHN_LIST: It is an array of index of each chain that is part of this scan structure. No particular order of the scan chain indexes is specified by the standard.

Chain Description Record (CDR)

Function: This record contains the description of a scan chain in terms of its input, output, number of cell and clocks. Each CDR record contains description of exactly one scan chain. Each CDR is uniquely identified by an index.

WARNING: THESE RECORDS COULD RESULT IN A EXTREMELY LARGE AMOUNT OF DATA VOLUME. PLEASE USE CAUTION.

Data Fields:

Field Names	Data Type	Field Description	Missing/Invalid Data Flag
REC_LEN:	U*2	Bytes of data following header	
REC_TYP:	U*1	Record type (1)	
REC_SUB:	U*1	Record sub-type (94)	
CONT_FLG	B*1	Continuation CDR record follows if not 0	
CDR_INDX	U*2	SCR Index	
CHN_NAM	C*n	Chain Name	Length byte = 0
CHN_LEN	U*4	Chain Length (# of scan cells in chain)	
SIN_PIN	U*2	PMR index of the chain's Scan In Signal	0
SOUT_PIN	U*2	PMR index of the chain's Scan Out Signal	0
MSTR_CNT	U*1	Count (m) of master clock pins specified for this scan chain	
M_CLKS	mxU*2	Array of PMR indexes for the master clocks assigned to this chain	MSTR_CNT=0
SLAV_CNT	U*1	Count (n) of slave clock pins specified for this scan chain	
S_CLKS	nxU*2	Array of PMR indexes for the slave clocks assigned to this chain	SLAV_CNT=0
INV_VAL	U*1	0: No Inversion, 1: Inversion	255
LST_CNT	U*2	Count (k) of scan cells listed in this record	
CELL_LST	kxS*n	Array of Scan Cell Names	LST_CNT=0

Field Descriptions:

CDR_INDX:	This is a unique number assigned to each CDR. It is used by the SSR record to reference a particular CDR.
CHN_NAM:	This is an optional ASCII unique name for the scan chain (user defined or derived/copied from ATPG files).
TOTS_CNT:	The number of scan cells contained within the scan chain
LOCS_CNT:	The number of scan cells listed in this record (the others are listed in continuation SCR records)
SIN_PIN:	The PMR record index for the chain's Scan In signal
SOUT_PIN:	The PMR record index for the chain's Scan Out signal
MSTR_CNT:	The # of master clock pins assigned to the scan chain
SLAV_CNT:	The # of slave clock pins assigned to the scan chain
M_CLKS:	An optional array of PMR indexes for the chain's master clock pins The length of this array is specified in the MSTR_CNT field
S_CLKS:	An optional array of PMR indexes for the chain's slave clock pins The length of this array is specified in the SLAV_CNT field.
INV_VAL:	A Boolean value to indicate if the Scan_Out signal is inverted from the Scan_In signal. A 0 value indicated no inversion. A value of 255 indicates unknown status.
CELL_LST:	The array of scan cell names.

Appendix

A. ATDF Representation

ATDF is the ASCII representation of the binary STDF. ATDF representation will have the same format as the V4 specification i.e.

Field name: <Value>

....

....

....

Field name: <Value>

The field names are the names that are mentioned in the tables for each field. The value will be the value of each field.

B. Data Model to STDF Record Mapping Table

The following table shows the mapping of data model objects onto STDF record. Please note that the information in the data model object in some cases is spread over multiple STDF records

Data Object	Data Field	Mapped Record	Mapped Field	Note
Design Information				
	Design Netlist Name	MIR	DSGN_REV	
	Scan Structure Description	SSR		
	Scan Structure Name	SSR	SSR_NAM	
	Num of Scan Chains	SSR	CHN_CNT

C Application Primer and Examples

This section provides the reader with some usage examples of datalogging scan test failures using the new record structures available in STDF V4-2007.

The following depicts an example STDF record sequence for 2 devices where two scan tests are applied to each device.

<u>Record Type</u>	<u>Comments</u>
FAR	File Attributes Record (Required)
VUR	Version Update Record (Required for V4-2007)
MIR	Master Information File (Required)
PMR(s)	Signal Pin Records ^(note 1)
NMR	List of Scan out Pins using ATPG signal names ^(note 1)
PSR	Applies to test #1
PSR	Applies to test #2
PIR	Start of Device #1
STR	from scan test #1
STR(s)	From scan test #2 (2 records required because fail data > 65K bytes)
STR	From scan test #2, but with fail limits applied
PRR	End of Device #1
PIR	Start of Device #2
STR	from scan test #1
STR	from scan test #2
PRR	End of Device #2

(Note 1) Each PMR record defines a single signal's attributes and subsequent records will refer to these records by their 'PMR Index'. Downstream diagnostic tools will often need to reference the signal name used in the pattern source files (e.g. WGL or STIL). The NMR record is required in those cases where, for whatever reason, the PMR is not able to accommodate the ATPG signal name. The NMR will list those pins that may be referenced by the STR records (generally the "Scan out" pins) and provide the required ATPG signal name.

The Version Update Record (VUR)

VUR record enables downstream tools to quickly identify that this SDF file potentially contains Scan Test Failure information in it. It is a required record for the V4-2007 specification.

Table 8 - Version Update Record

VUR Field Name	Value	Comments
UPD_NAM	"V4-2007"	

Name Map Record (NMR)

If we assume that the PMR records (Pin Map Record) were unable to use the signals names specified in the ATPG pattern file (e.g. WGL or STIL) in their LOG_NAM fields, then a NMR record needs to be created. In this example the NMR record needs as a minimum to list all of the scan-out pins that will be subsequently referenced in the STR (Scan Test records). If there are any primary I/O pins that are tested in the test patterns they should also be included. (the safest bet would be just to include all I/O signals)

Table 9 - Name Map record

NMR Field Name	Value	Comments
CONT_FLG	0	No continuation records follow
TOTM_CNT	313	
LOCM_CNT	313	
PMR_INDEX	Numerical array	Array of 313 PMR indexes
ATPG_NAM	String array	Array of 313 signals names as they are referred to in the ATPG pattern files

Note: If the corresponding PMR record for any of these pins listed in the NMR record used the ATPG signal in its LOG_NAM field then listing it here again is optional.

Pattern Sequence Record (PSR)

One or more PSR records are required to convey the information to downstream tools about the files created by ATPG tools that were used to construct any specific scan test. In this example we have defined that test #1 and test #2 used a different set of or sequence of patterns files, thus a unique PSR record must be created for each test. In this example PSR #1 will be assumed to be small enough to fit in a single record, but we will spread out PSR#2 across two records for the sake of understanding the use of the CONT_FLG field. PSR record #1 will be created with the minimum amount of information required, and PSR record #2 will be filled out with all of the optional fields specified.

Table 10 - First Pattern Sequence Record

PSR Field Name	Value	Comments
CONT_FLG	0	No continuation records follow
PS_INDX	2	
PSR_NAM	“Single Pattern”	
OPT_FLG	16	All optional fields included. 1 st cycle is #1
TOTP_CNT	1	One ATPG pattern files in PSR #1
LOCP_CNT	1	One ATPF pattern files listed in this record
PAT_BGN	1	Pattern begins on cycle #1
PAT_END	7090000	Pattern ends on cycle # 7,090,000
PAT_FILE	“RXC3_STX_01.stil”	The ATPG files used to create the test pattern
PAT_LBL	“Pat1”	Pattern label used in test program
FILE_UID	“65E6”	Some form of file checksum (undefined)
ATPG_DSC	“Version 2.1”	Extracted from the ATPG file
SRC_ID	“PatExec_01”	Extracted from the ATPG file

The second PSR record (for test # 2) is depicted below in Table 11. Note that the optional field arrays PAT_LBL, FILE_UID, ATPG_DSC, and SRC_ID are not included in this record

Table 11 – Second Pattern Sequence Record

PSR Field Name	Value	Comments
CONT_FLG	0	No continuation records follow
PS_INDX	2	
PSR_NAM	“Large Pattern”	
OPT_FLG	31	No optional fields. 1 st cycle is #1
TOTP_CNT	5	Five ATPG pattern files in PSR #2
LOCP_CNT	5	Five ATPF pattern files listed in this record
PAT_BGN	222 14,180,243 25,878,764 35,095,785 50,339,306	Starting Cycles # for each of the 5 ATPG pattern files. Note that there were 221 cycles in the test patterns before the 1 st pattern began, and there are 21 cycles in between each pattern
PAT_END	14,180,221 25,878,742 35,095,763 50,339,284 59,201,805	Ending Cycles # for each of the 5 ATPG pattern files.
PAT_FILE	“RXC3_STF_01.stil” “RXC3_STF_02.stil” “RXC3_STF_12.stil” “RXC3_STF_07.stil” “RXC3_STF_05.stil”	List of the ATPG files names that were used to create the test patterns

Scan Test Record (STR)

Each failing test execution can create a STR record to contain some or all of the failing cycles detected in the test. In addition any desired prevalent test conditions associated with this test can be added. The amount of information logged in an STR record can be at a minimal a set of two data arrays (failing cycle # and failing pin #), or be expanded to include such additional data as captured data state, expected data state, as well as user defined data.. The tables on the following pages the following STR record configurations:

Table 12 demonstrates a minimum data set configuration logging only the failing cycles and pins on 3,300 failures. Table 13 and 14 demonstrates a larger case in which the number of failures (12,450) exceeded the 65K limit in a single record, thus requiring a second continuation STR record.. Note the values placed in certain fields in the continuation STR record that are “redundant” with those in the 1st record will be eliminated. The general rule is that for fields that don’t support multiple values for a single test execution, only the values in the 1st record are applicable. In addition to the CYC_OFST and PMR_INDX fields, we are also including the EXP_DATA (expect data) field in these records. The distribution of the data arrays across the two STR records is arbitrary. In this example we placed all of CYC_OFST field data in the first record, some of the PMR_INDX field data in the first record and the remaining in the second record, none of the EXP_DATA in the first record and all of it in the second record

Table 12 – First Scan Test record

Field Name	Value	Comments
CONT_FLG	0	No continuation records follow
TEST_NUM	1	
HEAD_NUM	1	
SITE_NUM	1	
PSR_REF	1	
TEXT_FLG	“”	
LOG_TYP	“Cycle/Pin”	
TEST_TXT	“Scan Test 1”	
ALARM_ID	“”	
PROG_TXT	“”	
RSLT_TXT	‘Failed’	
Z_VAL	4	
FMU_FLG	2	No FAL_MAP or MASK_MAP fields required
CYC_CNT	7,090,000	7,090,000 cycles in the test
TOTF_CNT	3,300	3,300 failures
TOTL_CNT	3,300	All 23,100 failures are being logged
CYC_BASE	0	
BIT_BASE	0	n.a. since BIT_POS field not being logged
COND_CNT	2	2 test condition entries in COND_LST
LIM_CNT	0	No LIM_INDX or LIM_SPEC fields required
CYC_SIZE	4	4 bytes per entry in CYC_OFST array
PMR_SIZE	2	2 bytes per entry in PMR_INDX array
CHN_SIZE	1	n.a. since CHN_NUM field is not logged
BIT_SIZE	1	n.a. since BIT_POS field is not logged
U1_SIZE	1	n.a. since USR1 field is not logged
U2_SIZE	1	n.a. since USR2 field is not logged
U3_SIZE	1	n.a. since USR3 field is not logged
UTX_SIZE	1	n.a. since USR_TXT field is not logged
COND_LST	“VCC1=1.2V” “VCC2=3.2V”	Two strings (2xC*n) listing the test conditions
CYCL_CNT	3,300	3,300 entries in CYCL_OFST
CYCL_OFST	Array	Array of 3,300 failing cycle #'s (4 bytes per entry)
PMR_CNT	3,300	3,300 entries in PMR_INDX
PMR_INDX	Array	Array of 3,300 failing PMR #'s (2 bytes per entry)
CHN_CNT	0	No CHN_NUM field
EXP_CNT	0	No EXP_DATA field
CAP_CNT	0	No CAP_DATA field
NEW_CNT	0	No NEW_DATA field
PAT_CNT	0	No PAT_NUM field
BPOS_CNT	0	No BIT_POS field
USR1_CNT	0	No USR1 field
USR2_CNT	0	No USR2 field
USR3_CNT	0	No USR3 field
TXT_CNT	0	No USER_TXT field

Table 13 – Second Scan Test Record

Field Name	Value	Comments
CONT_FLG	1	A continuation STR record follows
TEST_NUM	1	
HEAD_NUM	1	
SITE_NUM	1	
PSR_REF	2	We are using the test pattern defined in PSR #2
TEXT_FLG	“”	
LOG_TYP	“Cycle/Pin”	
TEST_TXT	“Scan Test 2”	
ALARM_ID	“”	
PROG_TXT	“”	
RSLT_TXT	‘Failed’	
Z_VAL	4	
FMU_FLG	2	
CYC_CNT	59,201,805	# of cycles in this test
TOTF_CNT	12,450	# of failures in this test
TOTL_CNT	12,450	All 12,450 failures will be logged (across both records)
CYC_BASE	0	
BIT_BASE	0	Immaterial since BIT_POS field not being logged
COND_CNT	2	2 test condition entries in COND_LST
LIM_CNT	0	
CYC_SIZE	4	4 bytes per entry in CYC_OFST array
PMR_SIZE	2	2 bytes per entry in PMR_INDX array
CHN_SIZE	1	n.a. since CHN_NUM field is not being logged
BIT_SIZE	1	n.a. since BIT_POS field is not being logged
U1_SIZE	1	n.a. since USR1 field is not being logged
U2_SIZE	1	n.a. since USR2 field is not being logged
U3_SIZE	1	n.a. since USR3 field is not being logged
UTX_SIZE	1	n.a. since USR_TXT field is not being logged
COND_LST	VCC1=1.0V VCC2=2.9V	Two strings (2xC*n) each listing a critical test condition
CYCL_CNT	12,450	Logging all of the failures in CYCL_OFST
CYCL_OFST	Array of U*4	Array of 12,450 failing cycle #'s
PMR_CNT	7,800	Only logging the 1 st 7,800 failures in PMR_INDX
PMR_INDX	Array of U*2	Array of failing pin references (PMR indexes)
CHN_CNT	0	No CHN_NUM field
EXP_CNT	0	No room to log any EXP_DATA in this record
CAP_CNT	0	No CAP_DATA field
NEW_CNT	0	No NEW_DATA field
PAT_CNT	0	No PAT_NUM field
BPOS_CNT	0	No BIT_POS field
USR1_CNT	0	No USR1 field
USR2_CNT	0	No USR2 field
USR3_CNT	0	No USR3 field
TXT_CNT	0	No USER_TXT field

Table 14 - Continuation of Second Scan Test Record

Field Name	Value	Comments
CONT_FLG	0	This record completes the data
TEST_NUM	1	
HEAD_NUM	1	
SITE_NUM	1	
PSR_REF	2	Same as 1 st record
TEXT_FLG	“”	
LOG_TYP	“”	Not necessary to replicate from the 1 st record
TEST_TXT	“”	
ALARM_ID	“”	
PROG_TXT	“”	
RSLT_TXT	“”	Not necessary to replicate from the 1 st record
Z_VAL	4	
FMU_FLG	2	
CYC_CNT	59,201,805	# of cycles in this test
TOTF_CNT	12,450	# of failures in this test
TOTL_CNT	12,450	All 12,450 failures will be logged (across both records)
CYC_BASE	0	
BIT_BASE	0	Immaterial since BIT_POS field not being logged
COND_CNT	0	We could add more conditions if desired
LIM_CNT	0	
CYC_SIZE	4	n.a. since we are not logging CYC_OFST this time
PMR_SIZE	2	2 bytes per entry in PMR_INDX array
CHN_SIZE	1	n.a. since CHN_NUM field is not being logged
BIT_SIZE	1	n.a. since BIT_POS field is not being logged
U1_SIZE	1	n.a. since USR1 field is not being logged
U2_SIZE	1	n.a. since USR2 field is not being logged
U3_SIZE	1	n.a. since USR3 field is not being logged
UTX_SIZE	1	n.a. since USR_TXT field is not being logged
COND_LST	“”	Not necessary to replicate from the 1 st record
CYCL_CNT	0	All failing cycles were logged in 1 st record
PMR_CNT	4,650	Remaining PMR failures not listed in 1 st record
PMR_INDX	Array of U*2	Array of 4,650 failing pin references (PMR indexes)
CHN_CNT	0	No CHN_NUM field
EXP_CNT	12,450	We will log all the EXP_DATA in this record
EXP_DATA	Array of B*1	Array of 12,450 failing characters
CAP_CNT	0	No CAP_DATA field
NEW_CNT	0	No NEW_DATA field
PAT_CNT	0	No PAT_NUM field
BPOS_CNT	0	No BIT_POS field
USR1_CNT	0	No USR1 field
USR2_CNT	0	No USR2 field
USR3_CNT	0	No USR3 field
TXT_CNT	0	No USER_TXT field

Additional Data Arrays Available in the STR Record

In addition to the arrays used in the previous example, there are other optional arrays that can be for logging either additional failure or other test information.

As shown in the example for Test #2, the optional **EXP_DATA** array was added to log the expected data state for each failure. The **CAP_DATA** array is intended for logging “captured” data its use is identical to that defined for the **EXP_DATA**. Generally the usage of **CAP_DATA** array is in a test specifically used for the capture of actual devices data independent of expect data, e.g. a “Scan Dump”

The **NEW_DATA** array is provided for the purpose of logging changes made to a pattern within the ATE test program that results in a difference from the original ATPG pattern. Its use is identical to that defined for the **EXP_DATA** and **CAP_DATA**. It may or not be used in conjunction with the **EXP_DATA** array which would contain the original pattern data. Generally the usage of this field is in a test specifically used for the one time recording of the pattern changes made to a specific test.

Finally, the **USER_TXT** array provides the facility to log a unique fixed string for each logged failure (the string length is set in the **TEXT_LEN** field).

In summary, the typical array combinations in an STR record are:

- 1) CYCL_OFST + PMR_INDX
- 2) CYCL_OFST + PMR_INDX + EXP_DATA
- 3) CYCL_OFST + PMR_INDX + CAP_DATA
- 4) CYCL_OFST + PMR_INDX + NEW_DATA
- 5) CYCL_OFST + PMR_INDX + EXP_DATA +NEW_DATA

Logging Changes Made to a Pattern

One of the other applications targeted by the STR record is the documentation of modifications made to a test pattern from the pattern data that was in the original ATPG files. Note that this only applies to modifications made to the ATPG patterns directly, not to patterns that are added before or after the pattern file (these are handled by the PAT_BGN and PAT_END field in the PSR record). The example in Table 15 documents the modifications of a test pattern from LH1X0HHLHH1X0 to LX1X0LHLHH1L0 using an STR record (only the relevant fields are listed)

Table 15 - STR Used to Document Pattern Changes

Field Name	Value	Comments
CONT_FLG	0	No continuation STR records follow
PSR_REF	1	Indicates which pattern is being modified
TEXT_FLG	“”	
LOG_TYP	“Pattern Mods”	
CYC_CNT	13	# of cycles in this test
TOTF_CNT	3	# of Changes in this test
TOTL_CNT	3	All 3 changes logged
CYC_SIZE	1	1 byte per entry in CYC_OFST array
PMR_SIZE -	1	1 byte per entry in PMR_INDX array
CYCL_CNT	3	
CYCL_OFST	2, 6, 12	Cycle #'s being modified
PMR_CNT	3	
PMR_INDX	23, 23, 23	All changes are on PMR #23
EXP_CNT	3	3 existing pattern data entries
EXP_DATA	H, H, X	Existing pattern data (bytes)
NEW_CNT	3	3 new pattern data entries
NEW_DATA	X, L, L	New pattern data

NOTE: Subsequently when an STR is being logged that uses the pattern that was modified, bit 4 of the **FMU_FLG** field should be set to “1” to indicate the test is being performed with modifications made to the original pattern.

Logging Pattern/Chain/Bit Data in an STR Record

The previous conventions were based on the tester capturing the cycle and pin # of a failure and logging the data in that format. The downstream tool would then, based on information provided in the PSR records, extract the Pattern/Chain/Bit information on which the diagnosis is performed. The facility for the logging of Pattern/Chain/Bit data directly in a Scan Test record record is facilitated by the **PAT_NUM**, **CHN_NUM**, and **BIT_POS** fields. The **PAT_NUM** array would contain a list of pattern and the **BIT_POS** array would contain the bit position within the chain. Recall that the convention of starting the pattern numbers, chain numbers, and bit position numbers at 0 or 1 are specified in the relevant PSR's **OPT_FLG** field.

One of the problems to solve when using this format is how to identify the failing file when the test is a sequence of multiple pattern files. One approach is just to concatenate the pattern numbering so that the 1st pattern in the 2nd file start after the highest pattern # in file #1. A preferred alternative might be to start the pattern numbering over at "0/1" on each file. To indicate when a new file starts a proposed convention would to indicate this by inserting a "file change marker" entry into the fields. This could be done by inserting an entry in the **PAT_NUM** array of of the highest possible integer value (e.g. 255, 65535, etc.) and a corresponding file number in the corresponding **BIT_POS** entry.

This format can be use either the **PMR_INDX** or **CHN_NUM** field to specify which pin/chain the failure was on.

Using the User Defined Data Arrays in an STR Record

The user may include up to four optional generic data arrays to an STR file logging user specific data. These are the **USR1**, **USR2**, **USR3**, and **USER_TXT** fields. Each of the 1st three fields can be specified as 1, 2, 4, or 8 bytes per entry. The **USER_TXT** field contains a list of fixed length strings, where the # of characters per entry is specified in the **UTX_SIZE** field.

Logging Failures by Scan Cell Name in an STR Record

There are two provisions provided for logging explicit scan cell failures by name. The simplest (but most memory intensive) is to insert a string entry into the **USER_TXT** array for each failure.

A more efficient method of logging explicit scan cells failures is to create a **ScanCell Name Record (CNR)** for each scan cell failure observed (the same **CNR** record can be referenced each time it fails) The structure of a **CNR** record is:

CNR

CHN_NUM	= Chain number
BIT_POS	= Scan cell position in chain
CELL_NAM	= Scan cell Name

Notes:

CHN_NUM would be referenced by the CHN_NO array in an STR record
BIT_POS would be referenced by the BIT_POS array in an STR record

The FMU_FLG, MASK_MAP, and FAL_MAP Fields

The **STR** record provides three fields (two of which are optional) that provide additional information to downstream diagnostic tools about the failure attributes of specific signal pins.

The **MASK_MAP** field will specify which signals have been masked off in this specific test

The **FAL_MAP** field will specify which signals have additional failures that were detected beyond what was logged in the data arrays.

These presences of the **MASK_MAP** and **FAL_MAP** arrays are optional and their attributes are declared in the **FMU_FLG** field. (Note: that bit 4 of the **FMU_FLG** field is used to indicate that patterns have been modified)

The set of available field attributes for the **MASK_MAP** field are:

- No pins are masked and the **MASK_MAP** field is not present in this record
- Some pins are masked and the **MASK_MAP** field is present in this record
- Some pins are masked and the masked pins were specified in the **MASK_MAP** field contained in a previous STR record used for this same test suite. The field is not replicated in this STR record again (the information is “inherited” form the last STR applicable to this test)

The set of available field attributes for the **FAL_MAP** field are:

- No information on any potential additional failures after the last logged failure is available and the **FAL_MAP** field is not present in this record
- All failures were logged thus the **FAL_MAP** field is not present in this record
- They were some pins that have failures beyond what was logged and those pins are specified in the **FAL_MAP** field included in this record.

Refer to the Scan Test Record description to see how these various options are specified in the **FMU_FLG** field.

The LIM_CNT, LIM_INDX, and LIM_SPEC Fields

The **STR** record provides three fields (two of which are optional) that provide additional information to downstream diagnostic tools about the failure logging characters of specific signal pins.

The **LIM_INDX** array contains a list of pins (via their PMR indexes) that have unique maximum failure limits that were imposed by the tester for this specific test.

The **LIM_SPEC** array contains a list of the maximum failure limits imposed by the tester for this test. Each entry is the maximum failure limit imposed on the corresponding pin in the **LIM_INDX** array. If the 1st entry in **LIM_INDX** is= 0 (an otherwise invalid PMR index) then this indicates that the first specification listed in the **LIM_SPEC** array is the “default limit” and will apply to all pins not otherwise explicitly listed in the **PMR_INDX** array.

The **LIM_CNT** field specifies the number of entries in the **LIM_INDX** and **LIM_SPEC** arrays.

Example: Assume that pin #17 has a maximum failure limit of 1000, pin #99 has a maximum failure limit of 1500, and all other pins have a maximum failure limit of 3000, the field values would then be:

LIM_CNT	= 3
LIM_INDX	= {0, 17, 99}
LIM_SPEC	= {3000, 1000, 1500}

Logging Scan Structure Information

The **SSR** and **CDR** records provide the ability to include scan chain structure information in an STDF file. Normally this information would be extracted from the ScanStructures block of a STIL file. These records are optional and are not referenced or required by any other record type in an STDF file. These records will tend to be very large and should only be considered if required by a downstream diagnosis tool.

The **SSR** (Scan Structure Record) contains the top level information of a scan structure and includes the following fields:

SSR_NAM = the name of the ScanStructure block
CHN_CNT = the number of chains in the block
CHN_LIST = the list of CDR (Chain Description Record) record indexes

A **CDR** (Chain Description Record) must be created for each chain in the structure. If listing all of the scan cell names (which is optional) multiple CDR records will be required to list all of the scan cell names that are present in one chain. One option to the user is to exclude the scan cell name list (by setting **FLOCS_CNT** = 0) to achieve smaller files but still provide the other chain information .

SCR_INDX = Scan chain index (as referenced by the CHN_LIST array)
CHN_NAM = Chain name
FTOTS_CNT = Chain length (# of scan cells in chain)
FLOCS_CNT = # of scan cells in chain listed in this record
SIN_PIN = Scan-in pin (PMR index)
SOUT_PIN = Scan-out pin (PMR index)
MSTR_CNT = # of master clocks used in this scan chain
FSLAV_CNT = # of slave clocks used in this scan chain
M_CLKS = List of master Clocks (PMR Indexes)
S_CLKS = List of slave clocks (PMR Indexes)
INVRT_FIG = Chain Inversion state (0 or 1)
CELL_LST = List of scan cell names

Note: The CELL_LST list is a “kxS*n” data type, which is a new data type added in STDF 4-2007. The “S*n” type provides allows strings longer then the 255 character limit imposed by the “C*n” data type.

Figure 9: Sample STDF V4-2007 File Structure
